1 Background

Count data, one of the most common data types in many fields. In personalized medicine and pharmacology, the analysis is relevant for numerous applications, such as cancer and ageing research and in the evaluation of drug efficacy [1–5]. By default it is assumed to follow the Poisson distribution. This assumption, however, may lead to biased results and faulty conclusions in data bodies with excess zero values (zero-inflation [6,7]), a variance larger than the mean (overdispersion), or both. In such cases, the standard assumption of a Poisson distribution would skew the estimation of mean and variance, and other models like the negative binomial (NB), zero-inflated Poisson or zero-inflated NB distributions should be employed. The model chosen has an influence on the parameter estimation (mean value and confidence interval). Yet the choice of the most suitable distribution model is not trivial. To support and simplify this process, we have implemented the countfitteR software, which is provided as an R package and a web server. We show the application of our software based on examples of count data from phenotypic imaging as used in radiomics and precision medicine: DNA double-strand breaks (DSBs) [8]. DSBs are a highly specific and sensitive molecular biomarker for monitoring DNA damage in cancer, aging research and the evaluation of drug efficacy, and are detected and quantified by foci formation in fluorescence microscopy. In analyzing a large number of datasets of a molecular pharmacological markers (phosphorylated Histone H2AX and p53 binding protein [9,10]), countfitteR demonstrated an equal or superior statistical performance compared to the usually employed two-step procedure, with an overall power of up to 98 %. In addition, it still gave information in cases with no result at all from the two-step procedure. In our data sample we found that the NB distribution was the most frequent, with the Poisson distribution taking second place. Originally designed for the analysis of foci in biomedical image data, countfitteR can be used in a variety of areas where non-Poisson distributed counting data is prevalent.

2 General information about the countfitteR graphical user interface

2.1 Charts

Each chart may be saved in the `.svg` (Scalable Vector Graphic) format. A download button is always located at the top of a chart.

2.2 Tables

Tables may be downloaded in a specified format or printed using the buttons at the top of the table.

2.3 Data upload

The data format suitable for upload is the `.csv` file, where a single column corresponds to a single count (Note: example files are included in the package). **Use raw counts instead a pivot table!** If your document does not have headers, specify it using the “Header” checkbox. In this case, **countfitteR** will automatically name your counts with the index number of a count prefixed by ‘C’.

2.4 Count data

This panel contains descriptive statistics and summaries of the input data. It consists of three subpanels:
1. *Count table*: the input dataset in the tabular format allowing sanity checks and manual modification. 2. *Summary*: summary statistics of the input data (respectively mean, standard deviation, median, median absolute deviate, minimum, maximum, number of elements).
3. *Distribution*: a bar chart of the counts distribution followed by a pivot table.

2.5 Fitted models

1. *Mean value estimates*: the estimated value of mean (λ) and its confidence intervals. The BIC indicates the most appropriate distribution.

2. *Coefficients*: coefficients of fitted models.
3. *Decision*: the most appropriate model and the strength of the evidence [11].

2.6 Compare distributions

The bar charts represent theoretical counts depending on the chosen distribution. Red dots describe the real number of counts. The visualized data is also available in the tabular format.

2.7 Settings

Separate experiments: if this checkbox is marked, the **countfitteR** assumes that experiments are separate and fits the distribution to each individually and independently. Otherwise, all counts are simultaneously fitted to a single model. It is more appropriate for situations, where there is assumption that all samples may be describe by the same distribution, for example in case of technical replicates.

Confidence level: the confidence level of confidence intervals.

Count distributions: count distributions fitted to data: Poisson, Negative Binomial, Zero-Inflated Poisson, Zero-Inflated Negative Binomial. Possible distributions are described further in the manual.

3 Usage of the countfitteR software via the R console

```
# Below is an example of how to work with the countfitteR software in the
# R environment. For a simple example data was simulated.
#
# Generate poisson (Poisson_data) and negative binomial (nBinomial_data)
# distributed count data in silico. Here 200 random integer numbers
# (= 200 cells) were generated for both distributions.
# The simulation was set to mimic data with a low number of counts (low number
# of foci per cell in average).

set.seed(007)
df <- data.frame(Poisson_data = rpois(200, 1.85),
                 nBinomial_data = rnbinom(200, 8.5, 0.8))

# Inspect the first 10 and last 10 data points via the head() and tail()
# functions, respectively.

head(df, n = 10)
```

```
##    Poisson_data nBinomial_data
## 1             6              3
## 2             1              0
## 3             0              0
## 4             0              3
## 5             1              2
## 6             3              2
## 7             1              1
## 8             5              1
## 9             1              7
```

```
## 10           2              1
```

```r
tail(df, n = 10)
```

```
##     Poisson_data nBinomial_data
## 191            1              3

4 Sample records of counting data

The countfitteRsoftware contains sample data sets of counting data. These were obtained from measurements on human cells. Further information about the data can be found in the documentation of the countfitteR-package.

- `case_study`: Short version of the 'case_study_FITC' for the biomarker phosphorylated Histone H2AX
- `case_study_all`: Case study with two fluorescent dyes (biomarker phosphorylated Histone H2AX & biomarker p53 binding protein)
- `case_study_APC`: Case study for APC dye for the biomarker p53 binding protein
- `case_study_FITC`: Case study for FITC dye for the biomarker phosphorylated Histone H2AX

```r
# Output the first five columns and rows measured values of the dataset
# `case_study_FITC`. Each measuring point of a data series corresponds to the
# number of gamma H2AX foci per cell (~> 0 = no foci per cell).

countfitteR::case_study_FITC[1:5, 1:5]
```

```

5 Overdispersion of count data

One of the important features of the Poisson distribution is the equality of variance and expected value. Although count data is commonly assumed to be Poisson-distributed, we often encounter overdispersed datasets, when the variance is bigger than the mean. Three distributions included in **countfitteR**: Zero-Inflated Poisson (ZIP), Negative Binomial (NB) and Zero-negative Binomial (ZINB) model overdispersed counts.

Overdispersion may be caused by the increased variability of counts, for example when a counting algorithm under- and overcounts. In such situation the data might have the NB distribution. The other cause of overdispersion is called zero-inflation and occurs in datasets, where some factor introduced faulty zeros. That means that some counts, regardless of their real state, are treated as zeros. In this case, data has the ZIP distribution. If both faulty zeros and increased variance affect the data, the ZINB distribution is the most appropriate.

5.1 Overdispersed count data distribution

Poisson and Negative Binomial distributions have the same expected value. In case of ZIP and ZINB, the expected value is smaller than the real average number of foci per cell.

Table S1: Expected value and variance of Poisson, ZIP, NB and ZINB distributions. λ: Poisson parameter (number of occurrences, e.g., average number of foci per cell). r: zero inflation (fraction of occurrences treated as zeros, e.g., fraction of cells treated by system as having no foci regardless of their real state). θ: dispersion parameter.

Distribution name	Expected value	Variance
Poisson	$E(X) = \lambda$	$\text{var}(X) = \lambda$
ZIP	$E(X) = (1-r)\lambda$	$\text{var}(X) = \lambda(1-r)(1+\lambda r)$
NB	$E(X) = \lambda$	$\text{var}(X) = \lambda + \frac{\lambda^2}{\theta}$
ZINB	$E(X) = (1-r)\lambda$	$\text{var}(X) = (1-r)\lambda\left(1 + r\lambda + \frac{1}{\theta}\right)$

Depending on the value of r the variance of ZIP and ZINB may be smaller or bigger than the variance of Poisson distribution. In case of the NB distribution, the variance is always bigger than for the Poisson distribution, although the difference becomes negligible, when the θ is much bigger than λ^2.

Parameters:

- λ - Poisson parameter (average number of foci per cell).
- r - zero inflation (fraction of cells treated by system as having no foci regardless of their real state).
- θ - dispersion parameter.

Usually the NB distribution is parameterized using μ and θ, but to make comparison clearer, we use λ instead of μ. In this parameterization, NB and ZINB are treated as the mixture of Poisson and Gamma (Γ) distributions.

Table S2: Probability mass functions of Poisson, ZIP, NB and ZINB distributions. λ: Poisson parameter (number of occurrences, e.g., average number of foci per cell). r: zero inflation (fraction of occurrences treated as zeros, e.g., fraction of cells treated by system as having no foci regardless of their real state). θ: dispersion parameter.

Distribution name	pmf
Poisson	$$P\{X=k\} = \frac{\lambda^k \exp^{-\lambda}}{k!}$$
Zero-inflated Poisson	$$P\{X=k\} = \begin{cases} r + (1-r)\exp^{-\lambda}, \text{if } k=0 \\ r\frac{\lambda^k \exp^{-\lambda}}{k!}, \text{if } k = 1, 2, \ldots \end{cases}$$
Negative Binomial	$$P\{X=k\} = \frac{\Gamma(\theta+k)}{\Gamma(\theta)k!}\left(\left(\frac{\theta}{\theta+\lambda}\right)^{\theta}\left(\frac{\lambda}{\theta+\lambda}\right)\right)^{k}$$
Zero-inflated Negative Binomial	$$P\{X=k\} = \begin{cases} r + (1-r)\left(\frac{\theta}{\theta+\lambda}\right)^{\theta}, \text{if } k=0 \\ (1-r)\frac{\Gamma(\theta+k)}{\Gamma(\theta)k!}\left(\left(\frac{\theta}{\theta+\lambda}\right)^{\theta}\left(\frac{\lambda}{\theta+\lambda}\right)\right)^{k}, \text{if } k = 1, 2 \end{cases}$$

5.2 Results of the simulation

Figure S1: Empirical power of countfitteR and two-step test for Poisson distribution. n: number of counts in the sample. λ: Poisson parameter (number of occurrences, e.g., average number of foci per cell).

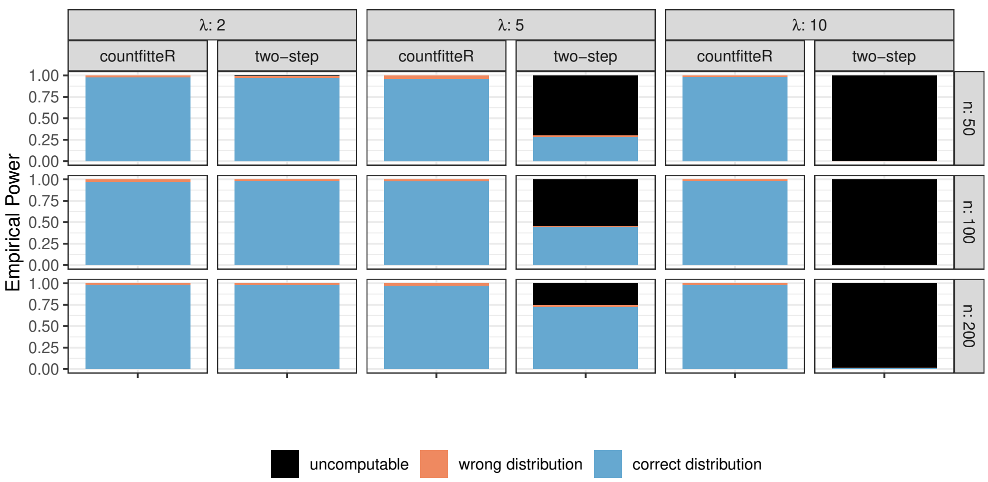

Figure S2: Empirical power of countfitteR and two-step test for NB distribution. λ: Poisson parameter (number of occurrences, e.g., average number of foci per cell). θ: dispersion parameter.

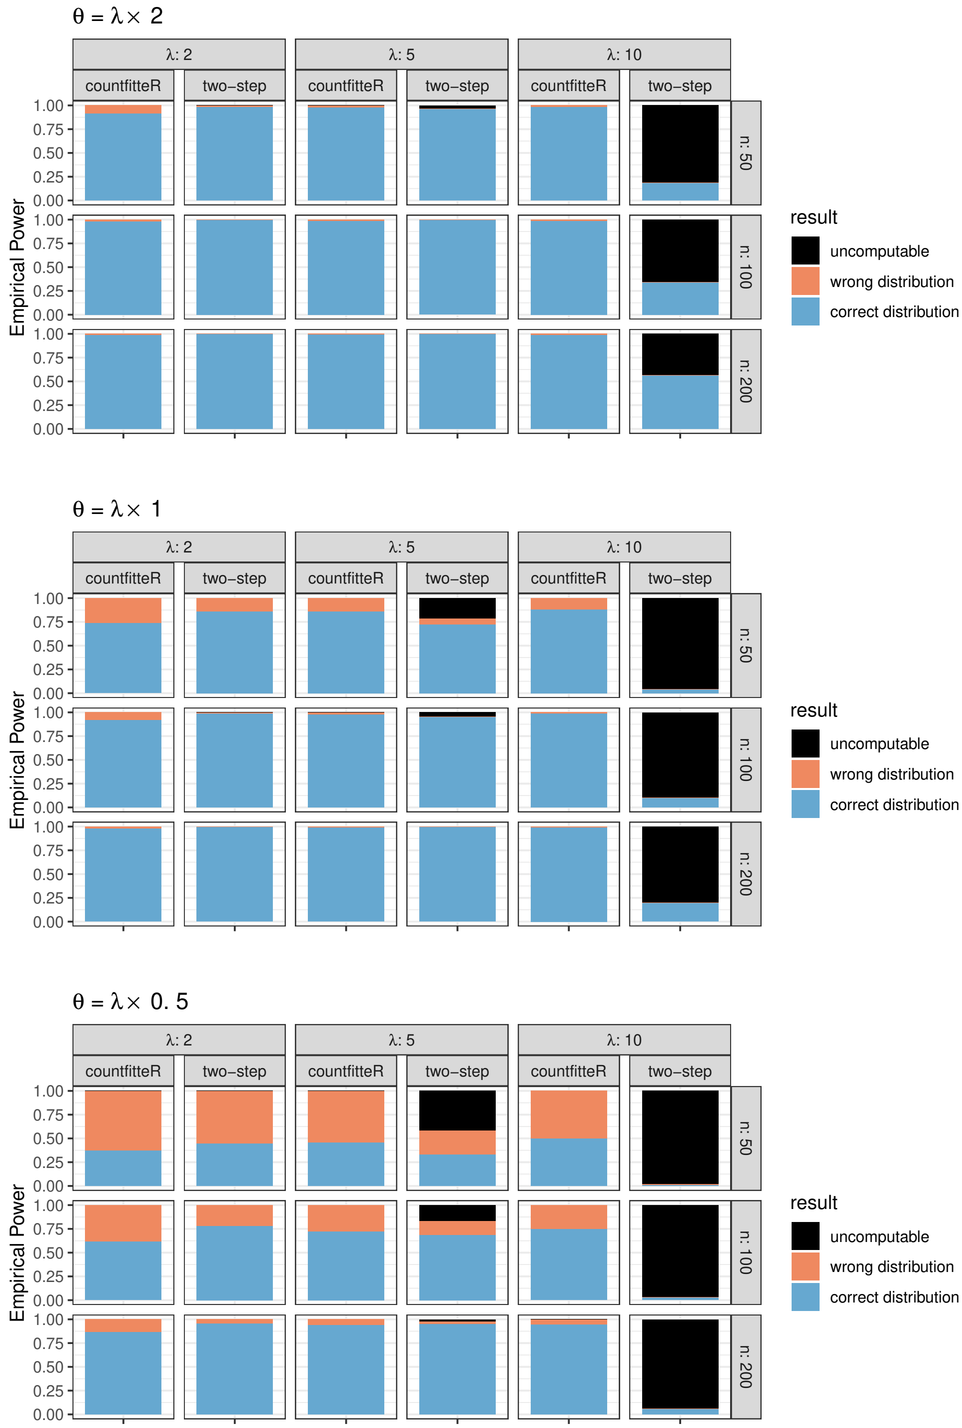

Table S3: Comparison of countfitteR empirical power with two-step procedure for Poisson distribution with three possible sample sizes (n = 50, 100, 200) and three possible means (λ = 2, 5, 10).
